# 1 Introduction

Camera calibration, also known as camera resectioning, is the process of determining the intrinsic and extrinsic parameters of a camera. The intrinsic parameters deal with the camera's internal characteristics, while the extrinsic parameters describe its position and orientation in the world. The knowledge of the accurate values of these values parameters are essential, as it enables us to create a mathematical model which describes how a camera projects 3D points from a scene onto the 2D image it captures. The importance of a well-calibrated camera becomes very apparent in photogrammetric applications, where precise measurements of 3-dimensional physical objects are derived from photographic images.

Photogrammetry is the science of obtaining accurate measurements of 3-dimensional physical objects through photographic imagery. Photogrammetry was first employed by Prussian architect Albrecht Meydenbauer in the 1860s, who used photogrammetric techniques to create some of the most detailed topographic plans and elevations drawings<sup>1</sup>. Today, photogrammetric techniques are used in a multitude of applications spanning diverse fields, including but not limited to: 3D-model generation, computer vision, topographical mapping, medical imaging, and forensic analysis.

While camera calibration is essential in ensuring the accuracy of photogrammetric applications, it itself also relies on these very same photogrammetric techniques in order to estimate these parameters. In essence, the developments of photogrammetry and camera calibration are closely intertwined, underscoring the essential relationship between photogrammetry and camera calibration.

## 1.1 Problem Statement

While manufacturers of cameras often report parameters of cameras, such as the nominal focal length and pixel sizes of their camera sensor, these figures are typically approximations which can vary from camera to camera, particularly in consumer-grade cameras. As such, the use of these estimates by manufacturers are unsuitable in developing camera models for

applications requiring high accuracy. Combined with the potential for manufacturing defects as well as unknown lens distortion coefficients further necessitates the need for a reliable method for determining the parameters of a camera.

Camera calibration emerges as the answer to these problems, allowing us to create very accurate models for the camera as well as generate estimates for its parameters. As such, it is important that we understand the mathematical techniques use in camera calibration, and why they find applications across many real-world applications.

## 2 Approach

There are a multitude of approaches one could take to calibrate cameras, and the choice of strategy significantly influences the complexity of the mathematical techniques that are used. The diversity in these approaches stems from the inherent complexity of cameras and the need for adaptable methods to address specific goals and constraints of each application. Notably, the accuracy of the calibration is significantly influenced by how the camera model is constructed, as well as the type of calibration used<sup>2</sup>.

### 2.1 Camera Model

A camera model is a projection model which approximates the function of a camera by describing a mathematical relationship between points in 3D space and its projection onto the sensor grid of the camera. In order to construct such a model, we must first understand the general workings of a camera.

The modern lens camera is highly sophisticated, built with an array of complex mechanisms and a wide range of features such as zoom and autofocus. However, we only need to focus on its three principal elements critical to image projection: the lens, the aperture, and the sensor grid (CCD).

- **Lens** – Focuses incoming light rays and projects it onto the sensor grid. Modern

---

cameras have compound lenses (lenses made up of several lens elements) in order to minimize undesired effects such as aberration, blurriness, and distortion.

- **Aperture** – Controls the amount of light that reaches the sensor. By adjusting the aperture size, the exposure and depth of field can be modified.
- **Sensor Grid** – Captures incoming light rays and converts this information into pixels on an image.

**Figure 2.1:** Lens camera. Adapted from John Colton, “Physics 123 Lecture 30 Warm-up Questions,” BYU Physics and Astronomy, November 5, 2012, accessed October 17, 2023, <https://physics.byu.edu/faculty/colton/docs/phy123-fall12/jitt30a.html>.

However, it is impossible to construct a model which is both simple and exact for the lens cameras, as the behavior of lenses are very complex. As such, it is mathematically convenient to approximate the camera as a pinhole camera. In doing so, we ignore lens distortion, but it distills the behavior of a camera to its most fundamental and essential dynamics: the projection of points in 3D space onto the flat 2D image plane.

### 2.1.1 Pinhole Camera Model

A pinhole camera is a simple camera without a lens. It instead relies on the use of a tiny hole as the aperture of the camera, and light rays pass through the hole, projecting an inverted image onto the image plane. The pinhole camera model is based on the pinhole camera, however it goes further by making the assumption that the aperture is infinitely small. This

means that any incoming light ray would only travel in straight lines, going through the pinhole mapping to one singular point on the image plane.

**Figure 2.2:** Difference between a pinhole camera and a lens camera. Adapted from Hoàng-Ân Lê, “Camera Model: Intrinsic Parameters,” July 30, 2018, accessed October 14, 2023, <https://lhoangan.github.io/camera-params/>.

If necessary, one could reintroduce distortion and shear terms in order to minimize the error, but this is often not needed for low to medium precision applications, as the distortion of modern lenses are already minimal. As such, its ease of use has led it to become one of the most frequently employed camera models in the field of camera calibration.

## 2.2 Calibration Object

The calibration object is an object with known dimensions and features which is often employed in camera calibration to establish a mapping between the 3D world and 2D image space. By capturing images of the calibration object, one can establish correspondences between points in the scene and pixels in the images, which can then be used to deduce the camera’s intrinsic and extrinsic parameters. Calibration objects can be constructed in many ways, and they can be separated into different categories based the dimension of the

calibration object<sup>3</sup>.

- **3D object based calibration** – Performed by using a calibration object whose geometry is known to very high precision. Typically, the calibration object consists of 2 or 3 orthogonal planes, although a plane whose precise translation is known may also be used, which also yields 3D reference points<sup>4</sup>. Using 3D objects is typically preferred, as it yields the highest accuracy<sup>5</sup>, and the mathematics required is the simplest.
- **2D plane-based calibration** – The most common technique is known as Zhang’s method, and it requires a planar object (often a checkerboard pattern), and various pictures of this plane are taken at different orientations<sup>6</sup>. Knowledge of the translation of the plane is not necessary. Due to its easier setup and good accuracy, it is the best choice in most situations. In fact, the most commonly used camera vision programming library, **OpenCV**, is geared towards this type of calibration.
- **1D line-based calibration** – Typically requires analyzing more than three photographs with straight lines which are not parallel with each other<sup>7</sup>.

One can also calibrate cameras without a calibration object, using featuring tracking of objects in the scene to estimate camera parameters. This process is often referred to as self-calibration or auto-calibration. However, this is less preferable, as it involves a lot of estimation of parameters, which not only means that it is a more mathematically complex problem, it may not be able to achieve the accuracy of calibration using known calibration patterns<sup>8</sup>. As such, it is typically the only chosen when pre-calibration is impossible.

<sup>8</sup>Zhang, “Camera Calibration.”

For this paper, I will focus on calibration using a 3D calibration object, because the mathematics behind it is simpler, and the techniques used in 3D-based calibration are well-established. By concentrating on 3D-based calibration, this paper aims to leverage the simplicity and reliability of established mathematical methods, contributing to a better understanding behind the mathematical techniques and strategies employed in camera calibration.

### 3 Constructing the Pinhole Camera Model

At its core, the pinhole camera model is a mathematical model which describes how points in 3D space are projected onto a 2D plane. It defines the relationship between the 3D world, the pinhole camera, and the resulting 2D image.

**Figure 3.1:** Pinhole camera model.

#### 3.1 Nomenclature

- $f$  – the focal length of the camera.
- $p_w$  – the position vector of the point  $X$  in  $\mathcal{W}$ .
- $p_c$  – the position vector of the point  $X$  in  $\mathcal{C}$ .

- $\mathbf{p}_i$  – the position vector of the projection  $\mathbf{X}_i$  on the image plane relative to the principal point, which is where the optical axis intersects the image plane.
- $\mathbf{c}_w$  – the position vector of the pinhole in  $\mathcal{W}$ .

### 3.2 Coordinate Frames

To construct the pinhole camera model, we will need to define 4 different coordinate systems:

- **World Coordinate Frame ( $\mathcal{W}$ )** – Represents the 3D space of the scene being photographed, with respect to an origin which may be arbitrary and depends on the conventions chosen. Objects that are in the scene are defined with respect to this coordinate frame.
- **Camera Coordinate Frame ( $\mathcal{C}$ )** – Represents the 3D space of the scene with the pinhole (aperture) of the camera defined as the origin.
- **Image Coordinate Frame ( $\mathcal{I}$ )** – 2D plane representing the image sensor plane of the camera. The origin is the principle point of the image sensor, where the optical axis intersects the image plane.
- **Pixel Coordinate Frame** – 2D plane representing the position of pixels on the image sensor. It is the discrete version of the image coordinate frame. The unit of measure is pixels.

**Figure 3.2:** This workflow highlights the coordinate transformations that need to occur to project a point in the scene onto the image plane.

### 3.3 Intrinsic Parameters

Intrinsic parameters describe the internal characteristics of the camera. In other words, it dictates how in the 3D space are projected onto the image plane, i.e. the relationship between the position of  $\mathbf{X}$  to its projection on the image plane.

**Figure 3.3:** Perspective projection of the point  $\mathbf{X}$  onto the image plane  $\Pi$ .

When a straight line is drawn from  $\mathbf{X}$  to its projection  $\mathbf{X}_i$  through the aperture, it intersects the optical axis. Deconstructing this intersection in the  $x$  and  $y$  direction, pairs of similar triangles are formed, which relates  $x_i$  to  $x_c$  and  $y_i$  to  $y_c$ .

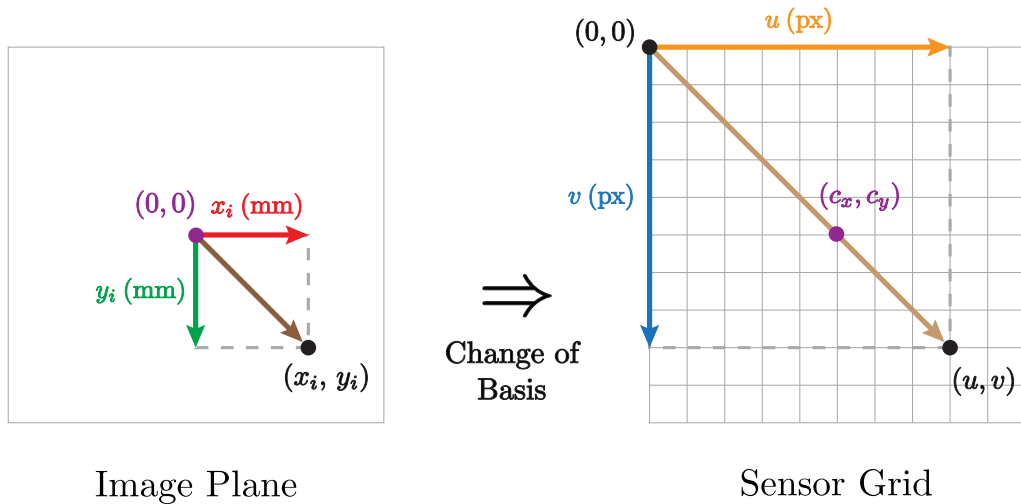

**Figure 3.4:** Similar triangles formed by perspective projection, which relate  $x_i$  to  $x_c$  and  $y_i$  to  $y_c$ .

$$\frac{x_i}{f} = \frac{x_c}{z_c} \implies x_i = f \frac{x_c}{z_c} \quad (3.1a)$$

$$\frac{y_i}{f} = \frac{y_c}{z_c} \implies y_i = f \frac{y_c}{z_c} \quad (3.1b)$$

Once the coordinates of the point projection,  $(x_i, y_i)$ , is known, we then need to convert it to actual pixel position of the point on the image,  $(u, v)$ . Pixel coordinates are measured in pixels, from the left-hand corner of the image. This is the convention that is typically followed in computer graphics. As such, there will be an offset in pixels,  $(c_x, c_y)$ , which represents the optical center of the image (i.e. the point at which the optical axis intersects the image plane). Additionally, the relationship between  $(x_i, y_i)$  and  $(u, v)$  is proportional, but they scale at different rates, as  $(x_i, y_i)$  can be measured using any unit measurement, and can have negative and decimal values. On the other hand,  $(u, v)$  are measured in discrete pixel value, which can be different sizes depending on the camera used. As such, we define scaling factors,  $m_x$  and  $m_y$ , which represent the pixel density of the image sensor in the  $x$  and  $y$  axes of the image sensor plane respectively.

**Figure 3.5:** Conversion from image plane coordinates to sensor grid coordinates

Putting all the ideas above together, we can construct a set of linear parametric equations relating the pixel coordinates to their image coordinates thus:

$$u = m_x x_i + c_x$$

$$v = m_y y_i + c_y$$

where  $u, v \in \mathbb{Z}_*^+$ . Replacing  $x_i$  and  $y_i$  for the result we obtained from equations 3.1a and 3.1b, we get:

$$u = m_x f \frac{x_c}{z_c} + c_x$$

$$v = m_y f \frac{y_c}{z_c} + c_y$$

This gives us a direct relationship between camera coordinates and their corresponding pixel coordinates. Since  $m_x$ ,  $m_y$ , and  $f$  are all unknowns, we can combine the products  $m_x f$  and  $m_y f$  into to  $f_x$  and  $f_y$  respectively. Under this new scheme, we define  $f_x$  and  $f_y$  as the horizontal and vertical focal lengths of camera.

$$u = f_x \frac{x_c}{z_c} + c_x \tag{3.2}$$

$$v = f_y \frac{y_c}{z_c} + c_y \tag{3.3}$$

Multiply both sides of the equations by  $z_c$ .

$$z_c u = f_x x_c + z_c c_x$$

$$z_c v = f_y y_c + z_c c_y$$

Doing so allows us to express the relationship as a matrix transformation using **homogenous**

**coordinates**<sup>9</sup>, by letting  $\tilde{w} = z_c$ .

$$\begin{bmatrix} z_c u \\ z_c v \\ z_c \end{bmatrix} = a \begin{bmatrix} f_x x_c + z_c c_x \\ f_y y_c + z_c c_y \\ z_c \end{bmatrix} = a \underbrace{\begin{bmatrix} f_x & 0 & c_x \\ 0 & f_y & c_y \\ 0 & 0 & 1 \end{bmatrix}}_K \begin{bmatrix} x_c \\ y_c \\ z_c \end{bmatrix}, \quad a \in \mathbb{R}; a \neq 0 \quad (3.5)$$

The equation includes a non-zero scale factor  $a$  because a property of homogenous coordinates is that multiplying the homogenous coordinate of a point by a non-zero scalar still represents the same point.

Equation 3.5 can be represented more simply thus:

$$\tilde{p}_i = aK p_c, \quad a \in \mathbb{R}; a \neq 0 \quad (3.6)$$

$K$  is known as the **calibration matrix**. It is a matrix transformation which maps a point represented in the camera coordinate frame to the coordinates of their projection onto the sensor plane. An important property worth noting is that  $K$  is an *upper triangular matrix*. It is a special kind of square matrix where all of its non-zero entries are above the main diagonal. This is an important property which we will exploit when extracting the  $K$  from the projection matrix in section 5.1.

### 3.4 Extrinsic Parameters

Extrinsic parameters describe the orientation of the camera. As such, they describe the relationship between the position of a point in the world coordinate frame and its coordinates in camera coordinates.

There are two possible types of movement affecting the orientation of the camera: rotation

---

<sup>9</sup>See Appendix A.

and translation. The rotation of the camera can be described using a  $3 \times 3$  square matrix:

$$R = \begin{bmatrix} r_{11} & r_{12} & r_{13} \\ r_{21} & r_{22} & r_{23} \\ r_{31} & r_{32} & r_{33} \end{bmatrix} \quad (3.7)$$

where:

- Row 1: Unit vector representing  $\hat{x}_c$  after rotation.
- Row 2: Unit vector representing  $\hat{y}_c$  after rotation.
- Row 3: Unit vector representing  $\hat{z}_c$  after rotation.

$R$  is an orthonormal matrix, because the row and column vectors of  $R$  have to be orthogonal. Orthonormality is important because it ensures that the scale of vectors do not change (meaning that determinant of  $R$  has to be 1) and that the orthogonality between vectors are maintained.

**Figure 3.6:** Coordinate transformation of  $\mathbf{X}$  from the world coordinate frame to the camera coordinate frame.

From Figure 3.6, we can see that the naive approach to finding the position vector of the

point in  $\mathcal{C}$  is equal to the position vector of the point in  $\mathcal{W}$  minus the position vector of the camera  $c_w$ . However, the camera can be facing in other directions, and we account for this rotation by including a rotational matrix in the equation. Thus:

$$\begin{aligned} p_c &= R(p_w - c_w) \\ &= R p_w - R c_w \end{aligned} \tag{3.8}$$

Since the position of the camera  $c_w$  is constant, we let  $t = -R c_w$ , and  $t$  represents the translation of the camera from the origin.

$$p_c = R p_w + t \tag{3.9}$$

This can be equivalently written as thus:

$$\begin{bmatrix} x_c \\ y_c \\ z_c \end{bmatrix} = \begin{bmatrix} r_{11} & r_{12} & r_{13} \\ r_{21} & r_{22} & r_{23} \\ r_{31} & r_{32} & r_{33} \end{bmatrix} \begin{bmatrix} x_w \\ y_w \\ z_w \end{bmatrix} + \begin{bmatrix} t_x \\ t_y \\ t_z \end{bmatrix}$$

We can then combine  $R$  and  $t$  into an augmented matrix,  $[R|t]$ , by expressing  $p_w$  in homogenous coordinates.

$$\begin{bmatrix} x_c \\ y_c \\ z_c \end{bmatrix} = \underbrace{\begin{bmatrix} r_{11} & r_{12} & r_{13} & t_x \\ r_{21} & r_{22} & r_{23} & t_y \\ r_{31} & r_{32} & r_{33} & t_z \end{bmatrix}}_{[R|t]} \begin{bmatrix} x_w \\ y_w \\ z_w \\ 1 \end{bmatrix} \tag{3.10}$$

Thus, we arrive at the final equation:

$$p_c = [R|t] \tilde{p}_w \tag{3.11}$$

## 4 Projection Matrix

When we combine the equation for the intrinsic transformation,  $\tilde{p}_i = aK p_c$  for  $a \in \mathbb{R}$  and  $a \neq 0$  (eq. 3.6), with the equation for the extrinsic transformation,  $p_c = [R | t] \tilde{p}_w$  (eq. 3.11), we obtain:

$$\tilde{p}_i = aK [R | t] \tilde{p}_w, \quad a \in \mathbb{R}; a \neq 0 \quad (4.1)$$

This single equation encapsulates the relationship between the world coordinates and its corresponding pixel coordinates. We can then further simplify our camera model by defining a new matrix,  $P$ , which is equivalent to the product  $K [R | t]$ . Since  $K$  is a  $3 \times 3$  matrix and  $[R | t]$  is a  $3 \times 4$  matrix, the matrix product  $K[R | t]$  yields a  $3 \times 4$  matrix.

$$\underbrace{\begin{bmatrix} p_{11} & p_{12} & p_{13} & p_{14} \\ p_{21} & p_{22} & p_{23} & p_{24} \\ p_{31} & p_{32} & p_{33} & p_{34} \end{bmatrix}}_P \equiv a \underbrace{\begin{bmatrix} f_x & 0 & c_x \\ 0 & f_y & c_y \\ 0 & 0 & 1 \end{bmatrix}}_K \underbrace{\begin{bmatrix} r_{11} & r_{12} & r_{13} & t_x \\ r_{21} & r_{22} & r_{23} & t_y \\ r_{31} & r_{32} & r_{33} & t_z \end{bmatrix}}_{[R | t]} \quad (4.2)$$

Replacing  $P$  for  $K [R | t]$  in equation 4.1, we obtain:

$$\tilde{p}_i = aP \tilde{p}_w \quad (4.3)$$

Equivalently:

$$\begin{bmatrix} \tilde{u}_n \\ \tilde{v}_n \\ \tilde{w}_n \end{bmatrix} = a \begin{bmatrix} p_{11} & p_{12} & p_{13} & p_{14} \\ p_{21} & p_{22} & p_{23} & p_{24} \\ p_{31} & p_{32} & p_{33} & p_{34} \end{bmatrix} \begin{bmatrix} x_w^{(n)} \\ y_w^{(n)} \\ z_w^{(n)} \\ 1 \end{bmatrix} \quad (4.4)$$

The implications of this equation is very important, as it means that a  $3 \times 4$  matrix is sufficient in describing the relationship between a point in the world coordinate frame to its projection onto the image plane in pixel coordinates.

## 4.1 Solving for the Projection Matrix

Now, we need to devise a way to solve for the projection matrix. Since we know that the projection matrix describes relationship between a point and their projection, we can go backwards and solve for the projection matrix given a set of points and their corresponding image projections. Rewriting the matrix equation 4.3 as a set of parametric equations and letting  $a = 1$  for now, we obtain:

$$\tilde{u}_n = p_{11}x_w^{(n)} + p_{12}y_w^{(n)} + p_{13}z_w^{(n)} + p_{14}$$

$$\tilde{v}_n = p_{21}x_w^{(n)} + p_{22}y_w^{(n)} + p_{23}z_w^{(n)} + p_{24}$$

$$\tilde{w}_n = p_{31}x_w^{(n)} + p_{32}y_w^{(n)} + p_{33}z_w^{(n)} + p_{34}$$

We convert the set of equations back to their inhomogeneous form by recognizing the fact that  $u_n = \tilde{u}_n/\tilde{w}_n$  and  $v_n = \tilde{v}_n/\tilde{w}_n$ .

$$u_n = \frac{p_{11}x_w^{(n)} + p_{12}y_w^{(n)} + p_{13}z_w^{(n)} + p_{14}}{p_{31}x_w^{(n)} + p_{32}y_w^{(n)} + p_{33}z_w^{(n)} + p_{34}}$$

$$v_n = \frac{p_{21}x_w^{(n)} + p_{22}y_w^{(n)} + p_{23}z_w^{(n)} + p_{24}}{p_{31}x_w^{(n)} + p_{32}y_w^{(n)} + p_{33}z_w^{(n)} + p_{34}}$$

For both equations, multiply both sides by the denominator.

$$u_n(p_{31}x_w^{(n)} + p_{32}y_w^{(n)} + p_{33}z_w^{(n)} + p_{34}) = p_{11}x_w^{(n)} + p_{12}y_w^{(n)} + p_{13}z_w^{(n)} + p_{14}$$

$$v_n(p_{31}x_w^{(n)} + p_{32}y_w^{(n)} + p_{33}z_w^{(n)} + p_{34}) = p_{21}x_w^{(n)} + p_{22}y_w^{(n)} + p_{23}z_w^{(n)} + p_{24}$$

Bringing all the terms onto one side:

$$0 = p_{11}x_w^{(n)} + p_{12}y_w^{(n)} + p_{13}z_w^{(n)} + p_{14} - p_{31}u_nx_w^{(n)} - p_{32}u_ny_w^{(n)} - p_{33}u_nz_w^{(n)} - p_{34}u_n \quad (4.5a)$$

$$0 = p_{21}x_w^{(n)} + p_{22}y_w^{(n)} + p_{23}z_w^{(n)} + p_{24} - p_{31}v_nx_w^{(n)} - p_{32}v_ny_w^{(n)} - p_{33}v_nz_w^{(n)} - p_{34}v_n \quad (4.5b)$$

We then need to recognize the fact that these two equations can be joined together to

form one matrix equation:

$$\begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} = \underbrace{\begin{bmatrix} x_w^{(1)} & y_w^{(1)} & z_w^{(1)} & 1 & 0 & 0 & 0 & 0 & -u_1 x_w^{(1)} & -u_1 y_w^{(1)} & -u_1 z_w^{(1)} & -u_1 \\ 0 & 0 & 0 & 0 & x_w^{(1)} & y_w^{(1)} & z_w^{(1)} & 1 & -v_1 x_w^{(1)} & -v_1 y_w^{(1)} & -v_1 z_w^{(1)} & -v_1 \\ & & & \vdots & & & & & & \vdots & & \\ x_w^{(n)} & y_w^{(n)} & z_w^{(n)} & 1 & 0 & 0 & 0 & 0 & -u_n x_w^{(n)} & -u_n y_w^{(n)} & -u_n z_w^{(n)} & -u_n \\ 0 & 0 & 0 & 0 & x_w^{(n)} & y_w^{(n)} & z_w^{(n)} & 1 & -v_n x_w^{(n)} & -v_n y_w^{(n)} & -v_n z_w^{(n)} & -v_n \end{bmatrix}}_G \begin{bmatrix} p_{11} \\ p_{12} \\ p_{13} \\ p_{14} \\ p_{21} \\ p_{22} \\ p_{23} \\ p_{24} \\ p_{31} \\ p_{32} \\ p_{33} \\ p_{34} \end{bmatrix} \quad (4.6)$$

$\underbrace{\hspace{10em}}_p$

where  $G$  is a  $2n \times 12$  matrix,  $n \in \mathbb{Z}^+$ , and  $p$  is the matrix vectorization of  $P$ . This system has 12 degrees of freedom, and since each point yields two equations, a minimum of 6 sets of points and their corresponding image projections are necessary in order to solve the system. When using 6 correspondences, a unique solution can be obtained using classical approaches, such as using **Gaussian elimination**. But since we want to minimize uncertainty and achieve a solution which is as accurate as possible, we want to use as many correspondences as possible.

When using more the 6 correspondences, we have more equations than unknowns. Such systems are *overdetermined*, and generally have no solutions<sup>10</sup>. However, we can optimize the system and obtain the "best approximate solution" using a method such as the **least-squares method**.

<sup>10</sup>Gareth Williams, "Overdetermined Systems of Linear Equations," *The American Mathematical Monthly* 97, no. 6 (June 1990): 511–513, accessed November 1, 2023, <https://www.jstor.org/stable/2323837>, JSTOR: 2323837.

## 4.2 Constrained Least-Squares Solution

First, we must clarify what a "best approximate solution" is.

**Definition 4.1** *Let  $A$  be an  $m \times n$  matrix and let  $b$  be a vector in  $\mathbb{R}^m$ . A **least-squares solution** of the matrix equation  $Ax = b$  is a vector  $\hat{x}$  such that:*

$$\text{dist}(b, A\hat{x}) \leq \text{dist}(b, Ax) \quad \forall x \in \mathbb{R}^n$$

The term least-squares solution comes from the fact that  $\text{dist}(b, A\hat{x}) = \|b - A\hat{x}\|$  is the square root of the sum of the squares of the entries of the vector  $b - A\hat{x}$ . In other words, a least-squares solution solve a matrix equation as closely as possible by minimizing the sum of the squares of the differences between the entries of  $A\hat{x}$  and  $b$ .<sup>11</sup>

Returning to our specific problem, we can apply least-squares method by minimizing  $\|Gp\|^2$ . We minimize  $\|Gp\|^2$  because we recognize that minimizing the square of the magnitude is equivalent to minimizing the magnitude itself, and that for a given vector  $v$ , it is easier to compute  $\|v\|^2$  instead of  $\|v\|$  since it eliminates the square root:

$$\|v\|^2 = \left( \sqrt{v_1^2 + v_2^2 + \cdots v_n^2} \right)^2 = v_1^2 + v_2^2 + \cdots v_n^2 = \begin{bmatrix} v_1 & v_2 & \cdots & v_n \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ \vdots \\ v_n \end{bmatrix} = v^T v$$

$v^T$  represents the *transpose* of  $v$ , i.e. swapping its rows and columns, transforming a row vector into a column vector or vice versa.

However, we need to further constrain the problem since the projection matrix  $P$  is applied onto homogenous coordinates, where the property holds that multiplying the homogenous coordinate of a point by a non-zero scalar still represents the same point<sup>12</sup>. This means that there is an infinite amount of solutions, because once we have found a valid solution for  $P$ ,

<sup>11</sup>Dan Margalit, Joseph Rabinoff, and Ben Williams, "7.5 The Method of Least Squares," in *Interactive Linear Algebra*, accessed December 25, 2023, <https://personal.math.ubc.ca/~tbjw/ila/ila.pdf>.

<sup>12</sup>See Appendix A.

we can always multiply  $P$  by a non-zero scalar  $k$  and still yield a valid solution, i.e.  $P \equiv kP$ . As such, any solution for  $P$  is only defined to a certain scale factor  $k$ . To mitigate this, we arbitrarily set the condition that  $\|p\|^2$  must equal 1. Thus:

$$\underset{p}{\text{minimize}} \quad \|Gp\|^2 \quad \text{subject to} \quad \|p\|^2 = 1$$

Or equivalently:

$$\underset{p}{\text{minimize}} \quad (p^\top G^\top G p) \quad \text{subject to} \quad p^\top p = 1 \quad (4.7)$$

The *Lagrangian*<sup>13</sup> of this equation is:

$$\mathcal{L}(p, \lambda) = p^\top G^\top G p - \lambda (p^\top p - 1) \quad (4.8)$$

where  $\lambda \in \mathbb{R}$  is the *Lagrange multiplier*. Since  $p$  is minimized when  $\mathcal{L}$  is minimized, we want to find the absolute minimum of  $\mathcal{L}$ . As such, we need to locate the critical points of  $\mathcal{L}$ . To find these points, we want to look for values of  $p$  and  $\lambda$  where all partial derivatives (denoted using  $\partial$ ) of the Lagrangian are zero.

$$\begin{aligned} \frac{\partial}{\partial p} \mathcal{L}(p, \lambda) &\stackrel{\text{set}}{=} 0 \\ \Rightarrow \frac{\partial}{\partial p} [p^\top G^\top G p - \lambda (p^\top p - 1)] &= 0 \\ \Rightarrow 2G^\top G p - 2\lambda p &= 0 \\ \Rightarrow G^\top G p &= \lambda p \end{aligned} \quad (4.9)$$

This equation is in fact in the form of the eigenvalue problem for  $G^\top G$ . Potential solutions for  $p$  are eigenvectors that satisfy equation 4.9, with the scalar  $\lambda \in \mathbb{R}$  as the eigenvalue. Since this is a minimization problem, the best approximate solution to  $p$  is the one which has the smallest  $\lambda$ .<sup>14</sup>

<sup>13</sup>Benyamin Ghogh, Fakhri Karray, and Mark Crowley, “Eigenvalue and Generalized Eigenvalue Problems: Tutorial,” Comment: 8 pages, Tutorial paper. v2, v3: Added additional information, May 20, 2023, 2, accessed October 21, 2023, <http://arxiv.org/abs/1903.11240>, arXiv: 1903.11240 [cs, stat].

<sup>14</sup>Ibid.

## 5 Extracting Parameters

Once we have solved for the projection for the projection matrix  $P$ , we can then decompose it and extract the intrinsic and extrinsic parameters.

$$\begin{aligned}
 P &= K [R \mid t] \\
 &= K [R \mid -Rc_w] \\
 &= [KR \mid -KRc_w]
 \end{aligned} \tag{5.1}$$

$$\tag{5.2}$$

### 5.1 RQ Decomposition

$$Q = \begin{bmatrix} p_{11} & p_{12} & p_{13} \\ p_{21} & p_{22} & p_{23} \\ p_{31} & p_{32} & p_{33} \end{bmatrix} = \underbrace{\begin{bmatrix} f_x & 0 & c_x \\ 0 & f_y & c_y \\ 0 & 0 & 1 \end{bmatrix}}_K \underbrace{\begin{bmatrix} r_{11} & r_{12} & r_{13} \\ r_{21} & r_{22} & r_{23} \\ r_{31} & r_{32} & r_{33} \end{bmatrix}}_R$$

Since  $K$  is in the form of an *upper right triangular matrix* and  $R$  is an *orthonormal matrix*, we can find unique solutions for  $K$  and  $R$  using a method called *RQ decomposition*.

*RQ decomposition* is a technique which allows us to uniquely decompose a matrix  $A$  into a product  $A = RQ$ , where  $R$  is an upper

Since

## 5.2 Extracting the Translation Vector

$$\begin{aligned}
 -Qc_w &= \begin{bmatrix} p_{14} \\ p_{24} \\ p_{34} \end{bmatrix} \\
 \Rightarrow c_w &= -Q^{-1} \begin{bmatrix} p_{14} \\ p_{24} \\ p_{34} \end{bmatrix}
 \end{aligned} \tag{5.3}$$

## 5.3 Extracting Orientation as Angles

When constructing the extrinsic matrix in section 3.4, we defined the rotation of the camera as a  $3 \times 3$  matrix, where the

We can represent the rotation in terms of *Tait-Bryan Angles*, where the rotation is represented as 3 elemental rotations about each of the principle axes.

$$R_x(\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos(\alpha) & -\sin(\alpha) \\ 0 & \sin(\alpha) & \cos(\alpha) \end{bmatrix} \tag{5.4a}$$

$$R_y(\beta) = \begin{bmatrix} \cos(\beta) & 0 & -\sin(\beta) \\ 0 & 1 & 0 \\ -\sin(\beta) & 0 & \cos(\beta) \end{bmatrix} \tag{5.4b}$$

$$R_z(\gamma) = \begin{bmatrix} \cos(\gamma) & -\sin(\gamma) & 0 \\ \sin(\gamma) & \cos(\gamma) & 0 \\ 0 & 0 & 1 \end{bmatrix} \tag{5.4c}$$

$$R \equiv R_z(\gamma)R_y(\beta)R_x(\alpha) \tag{5.5}$$

$$\begin{aligned}
R &= \begin{bmatrix} 0 & \cos(\alpha) & -\sin(\alpha) \\ 0 & \sin(\alpha) & \cos(\alpha) \\ 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} \cos(\beta) & 0 & -\sin(\beta) \\ 0 & 1 & 0 \\ -\sin(\beta) & 0 & -\cos(\beta) \end{bmatrix} \begin{bmatrix} \cos(\gamma) & -\sin(\gamma) & 0 \\ \sin(\gamma) & \cos(\gamma) & 0 \\ 0 & 0 & 1 \end{bmatrix} \\
&= \begin{bmatrix} \cos(\beta) \cos(\gamma) & \sin(\alpha) \sin(\beta) \cos(\gamma) - \cos(\alpha) \sin(\gamma) & \cos(\alpha) \sin(\beta) \cos(\gamma) + \sin(\alpha) \cos(\gamma) \\ \cos(\beta) \sin(\gamma) & \sin(\alpha) \sin(\beta) \sin(\gamma) + \cos(\alpha) \cos(\gamma) & \cos(\alpha) \sin(\beta) \sin(\gamma) - \sin(\alpha) \cos(\gamma) \\ -\sin(\beta) & \sin(\alpha) \cos(\beta) & \cos(\alpha) \cos(\beta) \end{bmatrix} \quad (5.6)
\end{aligned}$$

We have that

$$\begin{aligned}
r_{31} &= -\sin(\beta) \\
\Rightarrow \beta &= \sin^{-1}(-r_{31}) \quad (5.7)
\end{aligned}$$

$$\begin{aligned}
r_{32} &= \sin(\alpha) \cos(\beta) \\
\Rightarrow \alpha &= \sin^{-1} \left( \frac{r_{32}}{\cos(\beta)} \right) = \sin^{-1} \left( \frac{r_{32}}{\cos(\sin^{-1}(-r_{31}))} \right) \\
&= \sin^{-1} \left( \frac{r_{32}}{\sqrt{1 - r_{31}^2}} \right) \quad (5.8)
\end{aligned}$$

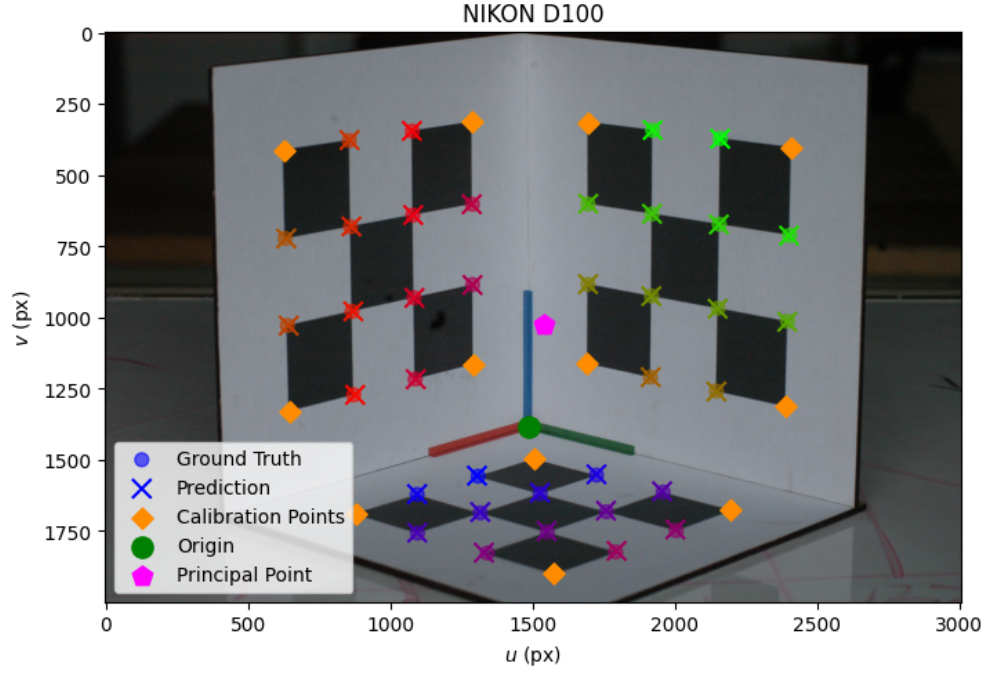

$$\begin{aligned}
r_{21} &= \cos(\beta) \sin(\gamma) \\
\Rightarrow \gamma &= \sin^{-1} \left( \frac{r_{21}}{\cos(\beta)} \right) = \sin^{-1} \left( \frac{r_{21}}{\cos(\sin^{-1}(-r_{31}))} \right) \\
&= \sin^{-1} \left( \frac{r_{21}}{\sqrt{1 - r_{31}^2}} \right) \quad (5.9)
\end{aligned}$$

## 6 Experimental Validation

In an attempt to show that the model works, I created the program

$$P = \begin{bmatrix} -2.5844 \times 10^{-3} & 1.7334 \times 10^{-3} & -4.6719 \times 10^{-4} & 6.0581 \times 10^{-1} \\ 4.8240 \times 10^{-4} & 4.4097 \times 10^{-4} & -3.1337 \times 10^{-3} & 7.9559 \times 10^{-1} \\ -3.3990 \times 10^{-7} & -3.1311 \times 10^{-7} & -2.8179 \times 10^{-7} & 4.1340 \times 10^{-4} \end{bmatrix}$$

## 6.1 Validating Estimated Focal Length

Given that specification of cameras are readily available online, we can actually evaluate the accuracy of our calculated focal lengths. Assuming that the pixels are square, we estimate the focal lengths of our cameras to be the average of the horizontal and vertical focal lengths. Then, based on the manufacturer reported size of each individual pixel (known as the *pixel pitch*), we can convert our estimated focal length from pixels to millimeters.

	Calculated Focal Length <sup>15</sup>	Manufacturer Reported Focal Length	% Error
Canon EOS D80	$(8496 \text{ px})(3.73 \times 10^{-3} \text{ mm/px}) \approx \boxed{31.7 \text{ mm}}$	32 mm	0.94 %
iPhone X	$(3280 \text{ px})(1.22 \times 10^{-3} \text{ mm/px}) \approx \boxed{4.00 \text{ mm}}$	4 mm	–
Nikon D100	$(8143 \text{ px})(7.82 \times 10^{-3} \text{ mm/px}) \approx \boxed{63.7 \text{ mm}}$	55 mm	15.6 %

**Table 6.2:** Comparison of Calculated vs. Reported Focal Length.

Considering that the focal lengths reported by manufacturers are often only accurate to around  $\pm 1 \text{ mm}$ ,<sup>16</sup> my results are very promising, with exception to the Nikon D100. However, this error is in fact a result of human error, as I forgot to turn off autofocus on the Nikon D100, and the zoom lens Nikon D100 altered the effective focal length.

## 7 Conclusion

From my rudimentary experimental validation, we can see that my devised method of camera calibration is very accurate, and despite its various limitations, such as fixed focal length and fixed locality, it serves as a proof of concept which excellently demonstrates the fundamental techniques behind camera calibration.

## Acknowledgements

I am very grateful to my supervisor Mr. Hoteit for his continual guidance and invaluable pieces of advice during the process of writing this extended essay. Additionally, I would like to express my appreciation to Mr. Auclair for dedicating his time to instruct me on camera operation and familiarizing me with camera settings. I am also indebted to Mr. Matthewson for his guidance with the manufacturing of my calibration object, and to Leon, for his help in operating the laser cutter. Last but not least, I want to thank Aditya for aiding me in the process of creating some of the diagrams used in my paper.

## Appendix A Homogenous Coordinates

The standard Cartesian coordinate system has long served as the foundation for representing points and vectors in Euclidean space. However, certain limitations arise when dealing with transformations, particularly translations and perspective projections, both of which are operations core to this paper. To overcome these challenges, homogenous coordinates are employed.

**Definition A.1** *Given a point  $(a_1, a_2, \dots, a_n) \in \mathbb{R}^n$ , it can be expressed in homogenous coordinates as  $(\lambda a_1, \lambda a_2, \dots, \lambda a_n, \lambda) \in \mathbb{R}^{n+1}$ , where  $\lambda \neq 0$  is a constant scale factor.*

In other words, we essentially extend the coordinate representation to include an extra dimension

$$\begin{bmatrix} u \\ v \end{bmatrix} \sim \begin{bmatrix} u\tilde{w} \\ v\tilde{w} \\ \tilde{w} \end{bmatrix} \equiv \begin{bmatrix} \tilde{u} \\ \tilde{v} \\ \tilde{w} \end{bmatrix} \quad (\text{A.1})$$

One important property of homogenous coordinates is that if the homogenous coordinate of a point is multiplied by a non-zero scalar, the result represents the same point. i.e.

$$\begin{bmatrix} \tilde{u} \\ \tilde{v} \\ \tilde{w} \end{bmatrix} \equiv k \begin{bmatrix} \tilde{u} \\ \tilde{v} \\ \tilde{w} \end{bmatrix} \quad (k \neq 0) \quad (\text{A.2})$$

**Figure A.1:** Homogenous coordinate system.
